# Logistic Regression

- Logistic regression is popular in bio-statistics and bio-informatics.
- Let  $\mathbf{x} \in \mathbb{R}^d$  be data and  $y \in \mathbb{R}$  be class label. Baye's rule:

$$\mathbb{P}(y|\mathbf{x}) = \frac{\mathbb{P}(\mathbf{x}|y)\mathbb{P}(y)}{\mathbb{P}(\mathbf{x})}, \quad (1)$$

where  $\mathbb{P}(y|\mathbf{x})$  and  $\mathbb{P}(\mathbf{x}|y)$  are the posterior and likelihood, respectively, and  $\mathbb{P}(\mathbf{x})$  and  $\mathbb{P}(y)$  are the priors.

- In contrast to Linear Discriminant Analysis (LDA), logistic regression works on the posterior  $\mathbb{P}(y|\mathbf{x})$  directly rather than working on likelihood  $\mathbb{P}(\mathbf{x}|y)$  and prior  $\mathbb{P}(y)$ .

# Logistic Regression

- Logistic regression is a binary classifier where it assigns probability between zero and one for belonging to one of the classes.
- The logistic function, used in logistic regression, was initially proposed in 1845 for modeling the population growth [1]. It was further improved in the 20th century [2]. See [3] for the history of logistic regression.
- It considers the classification problem as a regression problem where it regresses (predicts) the probability of belonging to a class. It first considers a linear regression  $\beta^T \mathbf{x} + \beta_0$ . However, in order to not have the bias, it assumes that  $\mathbf{x}$  is  $d + 1$  dimensional with an additional element of 1 for bias, i.e.,  $\mathbf{x} = [x_1, \dots, x_d, 1]^T$ . The  $\beta \in \mathbb{R}^{d+1}$  is the learnable parameter of the logistic regression model. As a result, the linear regression becomes  $\beta^T \mathbf{x}$ .
- However, there is no bound on this regression while logistic regression desires the output to be in the range  $[0, 1]$  to behave like a probability. Therefore, Logistic regression models the posterior using a logistic function, also called the sigmoid function, to make this regression between zero and one.

# Logistic Regression

- Assume we have two classes  $y \in \{0, 1\}$ .
- Logistic regression models the posterior using a **logistic function**, also called the **sigmoid function**:

$$\mathbb{P}(y = 1|X = x) = \frac{e^{\beta^\top x}}{1 + e^{\beta^\top x}}, \quad (2)$$

$$\mathbb{P}(y = 0|X = x) = 1 - \mathbb{P}(y = 1|X = x) = \frac{1}{1 + e^{\beta^\top x}}, \quad (3)$$

where  $\beta \in \mathbb{R}^d$  is the learnable parameter of the logistic regression model.

$$\frac{1}{1 + e^{-x}} \text{ (sigmoid)}$$

$$\frac{e^{\beta^\top x}}{1 + e^{\beta^\top x}}$$

$$\frac{1}{1 + e^{\beta^\top x}}$$

# Logistic Regression as a Neural Network

- Logistic regression can be seen as a neural network with one neuron where the activation function is the nonlinear sigmoid (logistic) function.

# Logistic Regression

- Consider  $n$  data points  $\{(x_i, y_i)\}_{i=1}^n$  in the dataset. Assuming that they are independent and identically distributed (i.i.d), the posterior over all data points is:

$$\mathbb{P}(y|X) = \prod_{i=1}^n \left( \mathbb{P}(y_i = 1|X = x_i)\mathbb{I}(y_i = 1) + \mathbb{P}(y_i = 0|X = x_i)\mathbb{I}(y_i = 0) \right), \quad (4)$$

where  $\mathbb{I}(\cdot)$  is the indicator function which is one if its condition is satisfied and is zero otherwise.

- As the labels are either zero or one, i.e.,  $y_i \in \{0, 1\}$ , this equation can be restated as:

$$\star \mathbb{P}(y|X) = \prod_{i=1}^n \left( \mathbb{P}(y_i = 1|X = x_i)^{y_i} \mathbb{P}(y_i = 0|X = x_i)^{1-y_i} \right). \quad (5)$$

- Substituting Eqs. (2) and (3) in this equation gives:

$$\star \mathbb{P}(y|X) = \prod_{i=1}^n \left( \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right)^{y_i} \left( \frac{1}{1 + e^{\beta^\top x_i}} \right)^{1-y_i}. \quad (6)$$

# Logistic Regression

- The log posterior is:

$$\begin{aligned}\ell(\beta) &:= \mathbb{P}(y|X=x) = \log \prod_{i=1}^n \left( \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right)^{y_i} \left( \frac{1}{1 + e^{\beta^\top x_i}} \right)^{1-y_i} \\&= \sum_{i=1}^n \left( \log \left( \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right)^{y_i} + \log \left( \frac{1}{1 + e^{\beta^\top x_i}} \right)^{1-y_i} \right) \\&= \sum_{i=1}^n \left( y_i \log(e^{\beta^\top x_i}) - y_i \log(1 + e^{\beta^\top x_i}) - (1 - y_i) \log(1 + e^{\beta^\top x_i}) \right) \\&= \sum_{i=1}^n \left( y_i \beta^\top x_i - y_i \log(1 + e^{\beta^\top x_i}) - \log(1 + e^{\beta^\top x_i}) \oplus y_i \log(1 + e^{\beta^\top x_i}) \right) \\&= \sum_{i=1}^n \left( y_i \beta^\top x_i - \log(1 + e^{\beta^\top x_i}) \right).\end{aligned}$$

# Logistic Regression

- The log posterior is:

$$\star \ell(\beta) = \sum_{i=1}^n \left( y_i \beta^\top x_i - \log(1 + e^{\beta^\top x_i}) \right).$$

- Newton's method can be used to find the optimum  $\beta$ . The first derivative, or the gradient, is:

$$\star \underbrace{\frac{\partial \ell(\beta)}{\partial \beta}} = \sum_{i=1}^n \left( y_i x_i - \frac{1}{1 + e^{\beta^\top x_i}} e^{\beta^\top x_i} x_i \right) = \sum_{i=1}^n \left( y_i - \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right) x_i. \quad (7)$$

Its transpose is:

$$\star \frac{\partial \ell(\beta)}{\partial \beta^\top} = \sum_{i=1}^n \left( y_i - \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right) x_i^\top.$$

# Logistic Regression

- The second derivative is:

$$\frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^\top} = \frac{\partial}{\partial \beta} \left( \frac{\partial \ell(\beta)}{\partial \beta^\top} \right) = \frac{\partial}{\partial \beta} \left( \sum_{i=1}^n \left( y_i - \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right) x_i^\top \right)$$

$$= \sum_{i=1}^n \left( - \frac{\partial}{\partial \beta} \left( \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}} \right) \right) x_i^\top.$$

- We define:

$$\star \quad \mathbb{P}(x_i | \beta) := \frac{e^{\beta^\top x_i}}{1 + e^{\beta^\top x_i}}. \quad \star \quad (8)$$

Therefore:

$$\star \quad \frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^\top} = - \sum_{i=1}^n \left( \frac{\partial}{\partial \beta} (\mathbb{P}(x_i | \beta)) \right) x_i^\top. \quad (9)$$

# Logistic Regression

- We have:

$$\begin{aligned}
 \star \quad \frac{\partial}{\partial \beta} (\mathbb{P}(\mathbf{x}_i | \beta)) &= \frac{\partial}{\partial \beta} \left( \frac{e^{\beta^\top \mathbf{x}_i}}{1 + e^{\beta^\top \mathbf{x}_i}} \right) \\
 &= \frac{1}{(1 + e^{\beta^\top \mathbf{x}_i})^2} \left( e^{\beta^\top \mathbf{x}_i} \mathbf{x}_i (1 + e^{\beta^\top \mathbf{x}_i}) - e^{\beta^\top \mathbf{x}_i} (e^{\beta^\top \mathbf{x}_i} \mathbf{x}_i) \right) \\
 &= \frac{e^{\beta^\top \mathbf{x}_i}}{(1 + e^{\beta^\top \mathbf{x}_i})^2} (1 + e^{\beta^\top \mathbf{x}_i} - e^{\beta^\top \mathbf{x}_i}) \mathbf{x}_i = \frac{e^{\beta^\top \mathbf{x}_i}}{(1 + e^{\beta^\top \mathbf{x}_i})^2} \mathbf{x}_i \\
 &= \frac{e^{\beta^\top \mathbf{x}_i}}{(1 + e^{\beta^\top \mathbf{x}_i})} \frac{1}{(1 + e^{\beta^\top \mathbf{x}_i})} \mathbf{x}_i \stackrel{(8)}{=} \mathbb{P}(\mathbf{x}_i | \beta) (1 - \mathbb{P}(\mathbf{x}_i | \beta)) \mathbf{x}_i
 \end{aligned}$$

- Substituting it in Eq. (9) gives the second derivative, i.e., the Hessian matrix:

$$\star \quad \frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^\top} = - \sum_{i=1}^n \left( \mathbb{P}(\mathbf{x}_i | \beta) (1 - \mathbb{P}(\mathbf{x}_i | \beta)) \mathbf{x}_i \right) \mathbf{x}_i^\top. \quad (10)$$

# Logistic Regression

- It is possible to write the Newton's method in matrix form. We define:

$$\mathbb{R}^{(d+1) \times n} \ni \mathbf{X} := \begin{bmatrix} x_1 & x_2 & \dots & x_n \\ 1 & 1 & \dots & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 & \dots & 1 \\ x_1 & x_2 & \dots & x_n \end{bmatrix}$$

$$\mathbb{R}^{n \times n} \ni \mathbf{W} := \text{diag}(\mathbb{P}(x_i|\beta)(1 - \mathbb{P}(x_i|\beta))),$$

$$\mathbb{R}^n \ni \mathbf{y} := [y_1, \dots, y_n]^T,$$

$$\mathbb{R}^n \ni \mathbf{p} := \left[ \frac{e^{\beta^T x_1}}{1 + e^{\beta^T x_1}}, \dots, \frac{e^{\beta^T x_n}}{1 + e^{\beta^T x_n}} \right]^T.$$

- The Eqs. (7) and (10) can be restated as:

$$\left\{ \begin{array}{l} \star \mathbb{R}^{(d+1)} \ni \frac{\partial \ell(\beta)}{\partial \beta} = \mathbf{X}(\mathbf{y} - \mathbf{p}), \\ \star \mathbb{R}^{(d+1) \times (d+1)} \ni \frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^T} = -\mathbf{X} \mathbf{W} \mathbf{X}^T. \end{array} \right. \quad \begin{array}{l} \rightarrow (\mathbf{X} \mathbf{W} \mathbf{X}^T)^{-1} \end{array} \quad (11)$$

$$\star \mathbb{R}^{(d+1) \times (d+1)} \ni \frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^T} = -\mathbf{X} \mathbf{W} \mathbf{X}^T. \quad (12)$$

- Using Newton's method for maximization of the log posterior is:

$$\begin{aligned} \beta^{(\tau+1)} &:= \beta^{(\tau)} + \left( \frac{\partial^2 \ell(\beta)}{\partial \beta \partial \beta^T} \right)^{-1} \frac{\partial \ell(\beta)}{\partial \beta} \Rightarrow \\ \beta^{(\tau+1)} &:= \beta^{(\tau)} + (\mathbf{X} \mathbf{W} \mathbf{X}^T)^{-1} \mathbf{X}(\mathbf{y} - \mathbf{p}), \end{aligned} \quad (13)$$

where  $\tau$  is the iteration index. It is repeated until convergence of  $\beta$ .

# Logistic Regression

- In the test phase, the class of a point  $x$  is determined as:

$$y = \begin{cases} 1 & \text{if } \frac{e^{\beta^T x}}{1 + e^{\beta^T x}} \geq 0.5, \\ 0 & \text{Otherwise.} \end{cases}$$

$P(Y=1 | X=x)$   
 $P(Y=0 | X=x) \quad (14)$

- Comparison to LDA: \*

- ▶ Logistic regression estimates  $(d+1)$  parameters in  $\beta$ , but LDA estimates many more parameters:

- ★ prior of each class: 1. We have two classes:  $2 \times 1 = 2$ .
- ★ mean of each class:  $d$ . We have two classes:  $2 \times d = 2d$ .
- ★ covariance matrix of each class:  $d(d+1)/2$ . We have two classes:  $2 \times (d(d+1)/2) = d(d+1)$ .
- ★ so, in total:  $2 + 2d + d(d+1) = d^2 + 2d + 2$ . \*

- ▶ LDA assumes the distribution of each class is Gaussian which may not be true. However, logistic regression does not assume anything about the distribution of data.
